

## Descriptive anatomy,

This historic book may have numerous typos and missing text. Purchasers can usually download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1910 edition. Excerpt: ... the coronoid process of the ulna during flexion, and the larger olecranon fossa behind, which receives the apex of the olecranon process of the ulna during extension. The external condyle, less prominent and forwardly inclined, shows in its articular portion the globular capitellum (little head), which articulates with the concavity on the summit of the radius, and is bounded internally by a shallow groove for the inner margin of the head of the radius, and above by the slight radial fossa for the anterior margin of the head of the radius in complete flexion of the forearm, while its non-articular portion shows the flat, irregular, forwardly-curved and smaller external epicondyle, which is continuous with the external supracondylar ridge, and gives origin above to the common tendon of the extensor carpi radialis brevis, extensor digitorum communis, extensor minimi digiti, extensor carpi ulnaris, and supinator, below and before to the external lateral ligament, and below and behind to the anconeus. The margins of the coronoid and olecranon fossae furnish attachment to the capsular ligament. The humerus develops from a primary center for the shaft and epiphyses for the extremities. The epiphysis for the superior extremity is formed by coalescence during the seventh year of secondary centers for the head, greater tuberosity, and lesser tuberosity, and joins the shaft about the twentieth year. The inferior extremity has two epiphyses, of which one, formed by the coalescence of secondary centers for the trochlea, capitellum, and external epicondyle, joins the shaft during the seventeenth year, whilst the other, comprising a secondary center for the internal epicondyle, joins the

shaft during the next year. \_ The two humeri may differ...
